Brand New Book ***** Print on Demand *****.This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1910 Excerpt: .of the speeds was 2:1. In the vapor of the arc, though, the negative were the faster. This may be clue to a falling off in speed as the positive go farther and farther from the center. So far only the most rapid ions of each class had been compared. But when the slower ions were considered the following results were obtained: (1) ions. (2) ions. The performer of these experiments then turns his attention to the discharge of hot platinum wires and of hot carbon and concludes that particles are emanated from the platinum and carbon. These particles when settling upon the negative ions retard their mo tion. His researches led to the belief also that the process of ionization may begin within the metal or the carbon itself. Perhaps occluded gases have something to do with it, and the arc in partial vacua also was studied. Without going into detail concerning the apparatus and its management, the results may be represented in Fig. 2--the irregular line showing a larger drop at the anode, a uniform fall in the space between the carbons and another abrupt fall at the cathode somewhat less than that at the anode. During these experiments an exhaust pump was connected (as shown) and pressures ranging from 730 to 2 mm. of mercury were obtained. The relative fall was always as indicated in the figure; but the drop at the negative carbon was greatest at a pressure of 100 mm. No...
